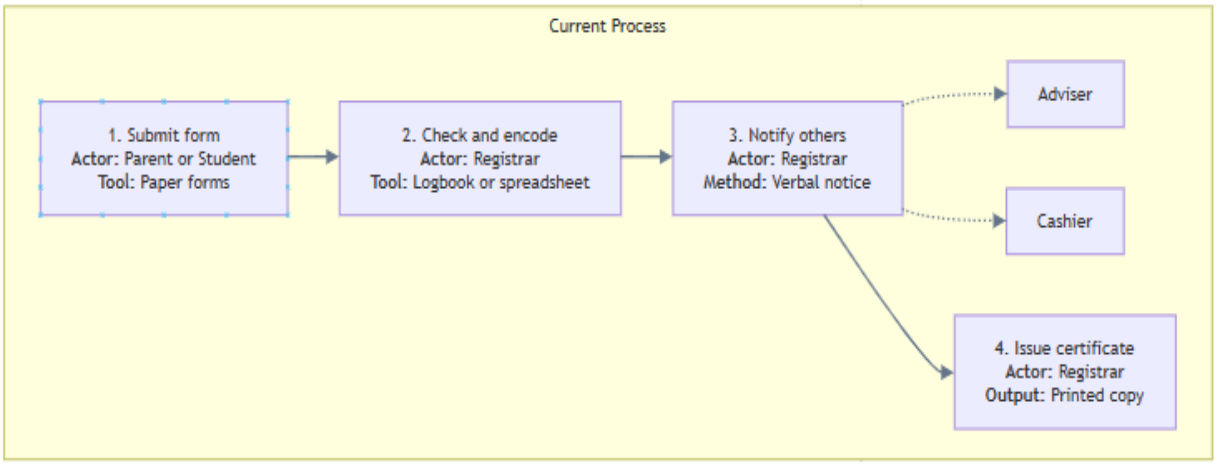

Mapping and Improving School Information Processes

Group formation and process list

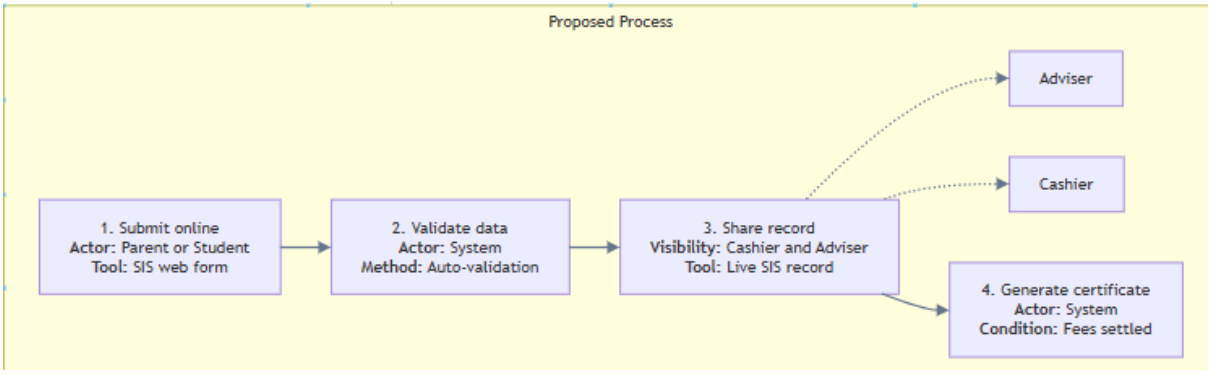

A typical school manages at least seven major processes: student enrollment and registration, class scheduling, attendance monitoring, grading and assessment, communication with parents, library services, and tuition and payment management. From this list, the group selected three processes for detailed study: student enrollment and registration, attendance monitoring, and tuition and payment management. These three were chosen because they touch nearly every student and family, carry the heaviest paperwork of any school office, and are the processes where a broken handoff between offices most directly affects a family, whether that means a student blocked from testing over a payment discrepancy or a parent who only learns about an attendance problem once it has already become serious.

Diagram 1: Student enrollment and registration

CURRENT

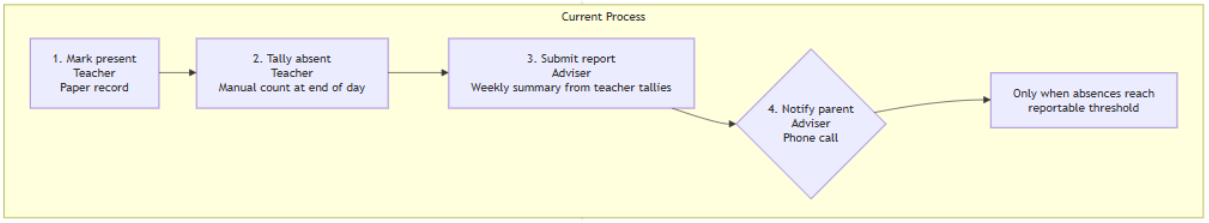

PROPOSE

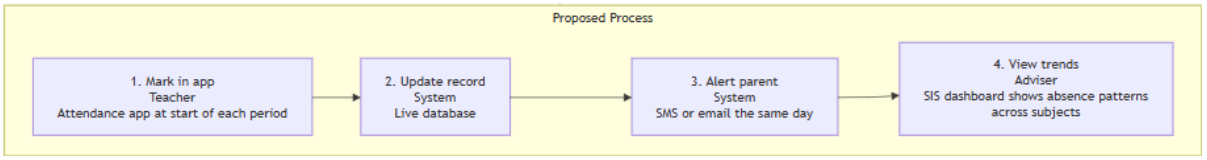

In the current process, a parent or student goes to the registrar's office, fills out a paper form by hand, and submits physical copies of documents such as the report card and birth certificate. The registrar checks these documents manually and encodes the data into a standalone spreadsheet or logbook that no other office can see. The cashier only learns about the new student when someone manually informs them to assess fees, and the adviser only finds out once class lists are compiled by hand at the end of the enrollment period, so the office most responsible for the student day to day is informed last. The proposed redesign moves this into a Student Information System: the family submits the form online with scanned documents, the system checks for missing fields before the registrar even reviews it, and once approved, that single record becomes instantly visible to both the cashier and the adviser at the same time, with the certificate of registration generated automatically once fees are settled.

Diagram 2: Attendance monitoring

CURRENT

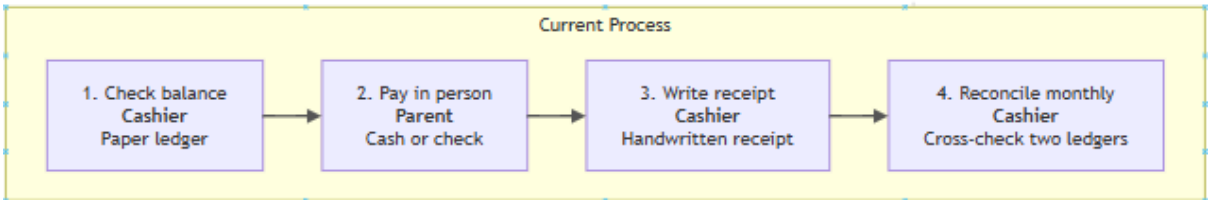

PROPOSE

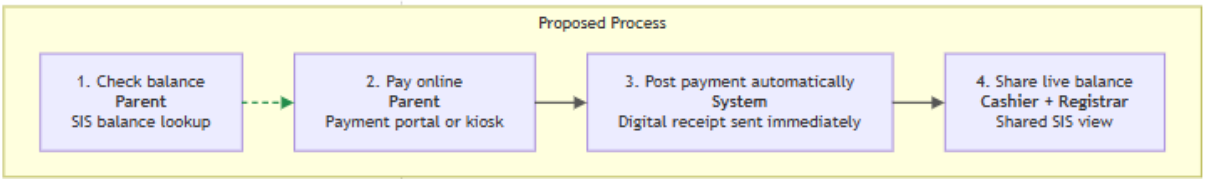

Right now, each teacher takes attendance on paper at the start of every period and tallies absences by hand at the end of the day, but that information only reaches the adviser or prefect of discipline once a week, and a parent typically only hears about it once absences accumulate to a reportable threshold, usually through a phone call or a note sent home with another student. By the time anyone acts, a student may have already missed a week or more of classes unnoticed. The redesign has each teacher log attendance directly into a system at the start of the period, which updates the adviser's record in real time and triggers a same-day SMS or email to the parent, while a dashboard lets the adviser spot absence patterns across subjects without compiling anything by hand.

Diagram 3: Tuition and payment management

CURRENT

PROPOSE

Currently, a parent pays at the cashier's window, where the cashier looks up the balance in a ledger kept separately from the registrar's enrollment record, receives cash or a check, writes a receipt by hand, and updates the ledger. At the end of the month, the cashier manually reconciles payments against enrollment records across two disconnected files, and the registrar is only informed of an unpaid balance once a discrepancy is manually flagged, sometimes only when the student tries to take an exam. In the proposed process, the cashier's terminal is linked to the same Student Information System as enrollment, so a parent can pay online, at a kiosk, or in person and have the payment posted against the correct balance immediately, with a digital receipt sent by email or SMS. Overdue balances are flagged and sent to both the parent and the registrar automatically, and both offices see the same live balance instead of relying on a monthly reconciliation.

Common findings and expected benefits

Across all three processes, the same underlying inefficiency appears: each office keeps its own separate record of the same student, so information has to be manually re-entered and manually passed along rather than shared instantly, and by the time a problem surfaces it is often already too late to act on quickly. Building all three processes around one shared system instead of isolated office records is expected to cut processing time in each workflow, reduce data entry errors from repeated manual encoding, get information to parents faster, and free office staff from reconciliation work that a connected system would otherwise handle automatically.
